

Dataset source: [Brazilian E-Commerce Public Dataset by Olist](https://www.olist.com)

Context

This dataset was generously provided by Olist, the largest department store in Brazilian marketplaces. Olist connects small businesses from all over Brazil to channels without hassle and with a single contract. Those merchants are able to sell their products through the Olist Store and ship them directly to the customers using Olist logistics partners. See more on our website: www.olist.com

After a customer purchases the product from Olist Store a seller gets notified to fulfill that order. Once the customer receives the product, or the estimated delivery date is due, the customer gets a satisfaction survey by email where he can give a note for the purchase experience and write down some comments.

Dataset schema:

Inspiration

Here are some inspiration for possible outcomes from this dataset.

1. **NLP:** This dataset offers a supreme environment to parse out the reviews text through its multiple dimensions.
2. **Clustering:** Some customers didn't write a review. But why are they happy or mad?
3. **Sales Prediction:** With purchase date information you'll be able to predict future sales.
4. **Delivery Performance:** You will also be able to work through delivery performance and find ways to optimize delivery times.
5. **Product Quality:** Enjoy yourself discovering the products categories that are more prone to customer dissatisfaction.
6. **Feature Engineering:** Create features from this rich dataset or attach some external public information to it.

❖ Files & Its overview

1. **olist_customers_dataset.csv:** This dataset has information about the customer and its location. Use it to identify unique customers in the orders dataset and to find the orders delivery location. At our system each order is assigned to a unique customer_id. This means that the same customer will get different ids for different orders. The purpose of having a customer_unique_id on the dataset is to allow you to identify customers that made repurchases at the store. Otherwise you would find that each order had a different customer associated with.

Here's the distinction:

- **customer_id**
→ A unique identifier for a **customer record/order session/account instance**.
→ The same real customer can appear multiple times with different customer_id values.
- **customer_unique_id**
→ A stable identifier representing the **actual unique customer/person** across purchases.
→ Used to identify repeat customers.

So in your case:

- customer_id unique count = **99,441**
- customer_unique_id unique count = **96,096**

This means:

- There are **96,096 real unique customers**
- But **99,441 customer records**
- Therefore, some customers appear more than once with different customer_ids.

The difference:

$$99441 - 96096 = 3345$$

So there are **3,345 extra customer records**, likely caused by repeat purchases or multiple registrations/orders linked to the same customer.

2. **olist_geolocation_dataset.csv** : This dataset has information Brazilian zip codes and its lat/lng coordinates. Use it to plot maps and find distances between sellers and customers.

3. **olist_order_items_dataset.csv** : This dataset includes data about the items purchased within each order.

Example:

The order_id = 00143d0f86d6fbd9f9b38ab440ac16f5 has 3 items (same product). Each item has the freight calculated accordingly to its measures and weight. To get the total freight value(transportation cost) for each order you just have to sum.

The total order_item value is: $21.33 * 3 = 63.99$

The total freight value is: $15.10 * 3 = 45.30$

The total order value (product + freight) is: $45.30 + 63.99 = 109.29$

4. **olist_order_payments_dataset.csv** : Contains about the about the orders payment options.

About columns in this:

- **payment_sequential:** a customer may pay an order with more than one payment method. If he does so, a sequence will be created to accommodate all payments.
- **Payment_type:** Refers type of payment method used like card,cash etc
- **payment_value:** Transaction value for payment.

5. **olist_order_reviews_dataset.csv** : This dataset includes data about the reviews made by the customers.

6. **olist_orders_dataset:** Contains order details

Column details:

- **order_approved_at:** Shows the payment approval timestamp.
- **order_delivered_carrier_date:** Shows the order posting timestamp. When it was handled to the logistic partner.
- **order_estimated_delivery_date:** Shows the estimated delivery date that was informed to customer at the purchase moment.

7. olist_products_dataset.csv : Tells about product details

Column details:

- **product_category_name:** root category of product, in Portuguese.
- **product_name_lenght:** number of characters extracted from the product name.
- **product_photos_qty:** number of product published photos

8. olist_sellers_dataset.csv: About seller details

9. product_category_name_translation.csv: Translation from Portuguese to english
